JANUARY 31, 2024 / #REACT

How to Implement Dynamic Segments with useParams in React Router

Alex Anie

The image features a dark background. On the left, there is a large blue React logo (an atom symbol). To its right is a white plus sign. Further right is a red and white abstract logo for 'React Router'. Below these icons, the text 'Dynamic Segments in React Router' is written in a large, bold, white sans-serif font.

On a traditional website, when a user clicks on a URL, the browser makes a full-page request from the server and directs the user to a new page. This is referred to as static routing.

This is very useful if you just need to navigate the user to a new page. But with the development of web apps, there's more need for pages to render on the client or load dynamically.

This involves updating particular parts of the URL called segments, as well as rendering new content or updating the content on the same page without making a request from the server or reloading the entire page.

Support our charity and our mission. Donate to [freeCodeCamp.org](#).

This can overall improve website performance and enable a good user experience.

In this tutorial, you'll learn about Dynamic Segments in React Router.

We'll go over what Dynamic Routing is and how it's different from Static Routing.

We'll also cover how to use `useParams` to enable Dynamic Segments, and how to set your path when getting data from an API.

Lastly, we'll build a new project that dynamically renders new content to the same page when the user clicks on the sidebar.

By the end of this guide, you should be able to implement dynamic segments on your own in your React app.

Prerequisites

To follow along, you'll need a basic knowledge of the following:

- React
- React-Router
- Tailwind CSS (optional)

Project Setup

To get started, create a folder called `dynamic-segment` and open it in VS Code (or your code editor of choice):

Next, click on `Ctrl + (backtick)` to launch the terminal as indicated above. This will enable us to install the npm packages we'll be using in this project.

Installations

Now that we have our project set up, let's install the `npm` packages that we need to get our project up and running.

Install React

React is a JavaScript library for building reusable and interactive components. To install it, copy and paste the command provided by [`vite.js`](#) below.

Support our charity and our mission. Donate to freeCodeCamp.org.

Then just follow the installing guide to finish the process. Once the installation is complete, the node_modules folder should be present in your project folder.

Install React Router

This is a React routing library for creating client-side routing applications. To install it, copy and paste the command below and press enter.

```
npm i react-router-dom
```

Install Feather Icon

Feather icon is a small yet beautiful collection of 24 x 24 grid open-source icons. It's built for adding flat icons on web applications.

To install it, paste the command below and press enter.

```
npm i react-feather
```

Install Tailwind CSS

Tailwind is a utility-first CSS framework for building beautiful and compact website designs. To install it, run the command on the terminal below.

```
npm install -D tailwindcss postcss autoprefixer
```

This will create a `tailwind.config.js` file. Next, generate your `postcss.config.js` files with the command below:

```
npx tailwindcss init -p
```

Support our charity and our mission. Donate to freeCodeCamp.org.

```
/** @type {import('tailwindcss').Config} */
export default {
  content: [
    "./index.html",
    "./src/**/*.{js,ts,jsx,tsx}",
  ],
  theme: {
    extend: {},
  },
  plugins: [],
}
```

Next, delete all CSS styles in the `./src/index.css` file and add the Tailwind directives `@tailwind` for each of Tailwind's layers.

```
@tailwind base;
@tailwind components;
@tailwind utilities;
```

Next, delete the `assets` folder, the `App.css` and `App.jsx` files from the `/src` folder. Once you've done that, configure the `main.jsx` files as the route component as indicated below:

```
import React from 'react'
import ReactDOM from 'react-dom/client'
import './index.css';

import {
  RouterProvider,
  createBrowserRouter,
  createRoutesFromElements,
  Route
} from 'react-router-dom';

const router = createBrowserRouter(
  createRoutesFromElements(
    <Route>
      <Route path="/" element={<p className='text-blue-700'>Hello, world</p>}></Route>
    </Route>
  )
)

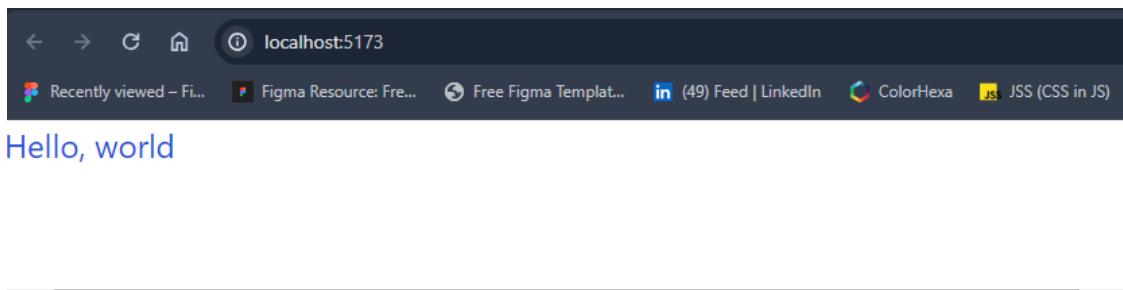

ReactDOM.createRoot(document.getElementById('root')).render(
  <React.StrictMode>
    <RouterProvider router={router} />
  </React.StrictMode>
)
```

Support our charity and our mission. Donate to freeCodeCamp.org.

Next, run the below command in the terminal to launch your app:

```
npm run dev
```

Your app should look like this in your browser:

Client-Side Routing

In React Router, navigation is relative between the `path` attribute and the `to` property. When a user clicks using the `<Link>` component (`<a>` tag), it navigates to the specified `path` within the route component and renders the component when it matches.

This type of navigation is called client-side routing because we are not rendering the pages from the server, but rather navigating from one component to another within the app.

The example below explains how client side routing works:

```
⚠ //main.jsx

import React from 'react'
import ReactDOM from 'react-dom/client'
import './index.css';
nt
import
{
  RouterProvider,
  createBrowserRouter,
  createRoutesFromElements,
```

Support our charity and our mission. Donate to freeCodeCamp.org.

```
const router = createBrowserRouter(
  createRoutesFromElements(
    <Route>
      <Route path='/' element={<Book />}></Route>
      <Route path='bookshop' element={<Bookshop />}></Route>
    </Route>
  )
)

ReactDOM.createRoot(document.getElementById('root')).render(
  <React.StrictMode>
    <RouterProvider router={router} />
  </React.StrictMode>,
)
```

From the code example above, we imported two components, `Book` and `Bookshop`, and link them via the `<a>` tag and the `Route` component on the `./src/main.jsx` component.

 //book.jsx

```
export default function Book() {
  return (
    <>
      <main className="px-4">
        <ul>
          <ol>77 Ways get to more customers By: <i>Ubuy</i></ol>
          <ol>Authenticity By: <i>Emanuel Rose</i> </ol>
          <ol> Change Your thinking change your life By: <i>Brian Tracy</i></ol>

          <button href="bookshop" className="text-blue-600 inline-block px-4 underline">
            /* <a href="publisher/itemId" className="text-blue-600 underline">Publis
          </ul>
        </main>
      </>
    )
}
```

The `href` attribute accepts the `bookshop` component as a relative path. So clicking the link should navigate you to the `bookshop` component.

 //bookshop.jsx

```
export default function Bookshop() {
  return (
```

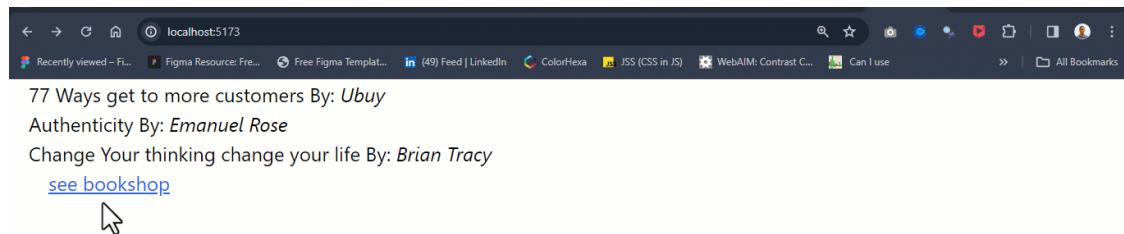

Support our charity and our mission. Donate to freeCodeCamp.org.

```
<li>Simon books</li>
<li>Dynamic Book home</li>
</ul>

👉 <a href="/" className="text-blue-600 inline-block px-4 underline">Names of Books</a>
</div>
)
}
```

The `href="/"` in the bookshop component specifies the index route and should navigate you back to the home components.

Your app should look like this on your browser – click to navigate to the bookshop component.

From the browser output above, you'll notice how the URL is updated from the address bar and a new component is rendered.

The type of routing is called client-side routing and only updates the URL path once with the new route.

In the next section, I'll explain how you can update a particular segment and render content dynamically.

Dynamic Segments

A Dynamic Segment, as the name suggests, is a way of rendering a new component (UI) by updating a particular segment in the URL called params. You use the `useParams` hook from `react-router-dom` to do this.

Support our charity and our mission. Donate to freeCodeCamp.org.

Continuing from where we stopped in the code, go to the `./src/main.jsx` component. Edit the Route and add `:itemId` to the path as indicated below:

```
⚠ //main.jsx

<Route>
  <Route path='/' element={<Book />}></Route>
  <Route path='bookshop' element={<Bookshop />} />
  👉 <Route path='publisher/:itemId' element={<Publisher />} />
</Route>
```

Note that the `:` in the `:itemId` URL segment means Dynamic Segment.

Next, create a new component as `./src/publisher.jsx` and add the code below:

```
⚠ //publisher.jsx

import { useParams } from "react-router-dom"

export default function Publisher() {
  const { itemId } = useParams();

  return (
    <>
    {
      itemId ? (
        <div>
          <h1>Book publishing companies</h1>
          <ul>
            <ol>Penguin Random House</ol>
            <ol>Scholastic</ol>
            <ol>LPI Media</ol>
          </ul>
        </div>
      ) : (
        <p>Page item is not present</p>
      )
    }
    </>
  )
}
```

Let's talk about what this code is doing:

Support our charity and our mission. Donate to freeCodeCamp.org.

- `itemID?():` here we conditionally render a list of bookshop companies when a clicked link matches the params.

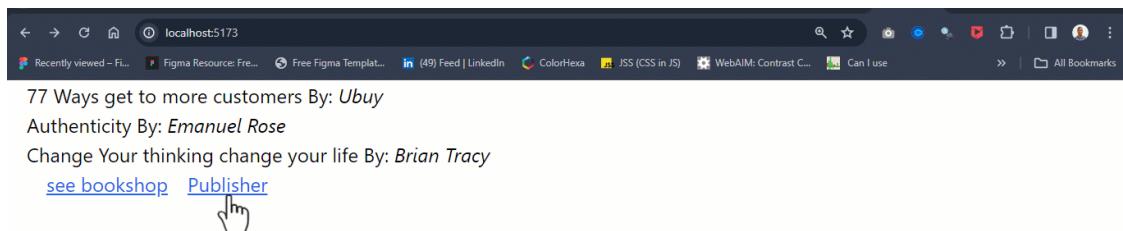

Next, in the `./src/book` component, include the `publisher/itemId` as indicated in the `<a>` tag below:

 //book.jsx

```
export default function Book() {
  return (
    <>
      <main className="px-4">
        <ul>
          <ol>77 Ways get to more customers By: <i>Ubuy</i></ol>
          <ol>Authenticity By: <i>Emanuel Rose</i> </ol>
          <ol> Change Your thinking change your life By: <i>Brian Tracy</i></ol>

          <a href="bookshop" className="text-blue-600 inline-block px-4 underline">
            ↗ <a href="publisher/itemId" className="text-blue-600 underline">Publisher
          </ul>
        </main>
      </>
    )
}
```

Your app should look like this in your browser:

Notice the update in the URL at the browser address bar.

Let's look at another example.

Support our charity and our mission. Donate to freeCodeCamp.org.

Let's see how this works. First, we need to decide where we will be fetching our data from. In this case, create an external JavaScript object `./scr/books.js` and copy and paste the code below:

```
⚠ //books.js

export default [
  { id: "1",
    title: "The Great Gatsby",
    author: "F. Scott Fitzgerald",
    year: "1925",
    description: "The Great Gatsby is a 1925 novel by American writer F. Scott Fitzgerald." },
  { id: "2",
    title: "Pride and Prejudice",
    author: "Jane Austen",
    year: "1813",
    description: "Pride and Prejudice is the second novel by English author Jane Austen." },
  { id: "3",
    title: "To Kill a Mockingbird",
    author: "Harper Lee",
    year: "1960",
    description: "To Kill a Mockingbird is a novel by the American author Harper Lee." },
  { id: "4",
    title: "Beloved",
    author: "Toni Morrison",
    year: "1987",
    description: "Beloved is a 1987 novel by American novelist Toni Morrison. Set in a small town in Ohio during the American Civil War, it explores the theme of the legacy of slavery." }]
```

Next, create a new component called `./src/FavBooks.jsx` and write in the code below:

```
⚠ //FavBooks.jsx

import { useParams } from 'react-router-dom';
import book from './book';

export default function FavBooks() {
  const {bookId} = useParams()
```

Support our charity and our mission. Donate to freeCodeCamp.org.

```

}
return (
  <>
  <main>
    {newFavBook && (
      <>
      <main>
        <p>{`Title: ${newFavBook.title}`}</p>
        <p>{`By: ${newFavBook.author}`}</p>
        <p>{`Year: ${newFavBook.year}`}</p>
        <p>{`Description: ${newFavBook.description}`}</p>
      </main>
      </>
    )}
  </main>
  </>
)
}

```

Next, go to the `./src/book.jsx` component and update the code as follows:

```

import { Link } from 'react-router-dom';
import books from './book.js';

export default function Books() {

  return (
    <>
    <div className='m-4'>
      <p className="text-3xl">{`List of my favourite books`}</p>
    </div>

    <div className='m-4'>
      {
        books && books.map((book)=> (
          <>
          <ul>
            <li>
              <Link to={`${newbooks}/${book.id}`}` className='text-blue-600 underline'>{book.title}</Link>
            </li>
          </ul>
        </>
      ))
    }
  </div>
)
}

```

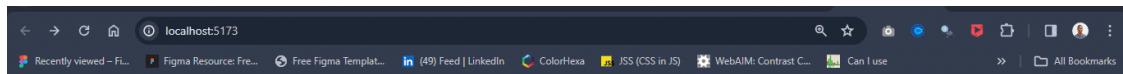

Support our charity and our mission. Donate to freeCodeCamp.org.

```
import Book from '../src/books';
import Bookshop from './bookshop';
import Publisher from './publisher';
👉 import FavBooks from './FavBooks';

const router = createBrowserRouter(
  createRoutesFromElements(
    <Route>
      <Route path='/' element={<Book />}></Route>
      <Route path='bookshop' element={<Bookshop />} />
      <Route path='publisher/:itemId' element={<Publisher />} />
👉 <Route path='newbooks/:bookId' element={<FavBooks />} />
    </Route>
  )
)
```

Your app should look like this in your browser:

List of my favourite books

[The Great Gatsby](#)
[Pride and Prejudice](#)
[To Kill a Mockingbird](#)
[Beloved](#)

From the browser output, the URL params are being updated with the path segment and the id values from the books.js object.

Try clicking on each of the titles and notice how the id of the books.js object is present in the URL.

When a user clicks the link, it renders a new UI on a new page. But there are cases where you might want to render the content of the API on the same page as list items, so the content doesn't have to open on a new page. To do this, we have to implement nested routing.

Nested Routing

Nested routing makes it possible to nest routes to render new components on the same page for easy navigation and quick interactivity of the element. Nested routes

Support our charity and our mission. Donate to freeCodeCamp.org.

Now let's see how to convert our little application to a nested route.

To go the `./src/main` component and create a nested route as follows:

```
const router = createBrowserRouter(
  createRoutesFromElements(
    <Route>

      <Route path='/' element={<Book />} >
        ↪ <Route path='newbooks/:bookId' element={<FavBooks />} />
      </Route>

      <Route path='bookshop' element={<Bookshop />} />
      <Route path='publisher/:itemId' element={<Publisher />} />
    </Route>
  )
)
```

Essentially, we are nesting the `FavBook` component to the `Book` component as its direct child, so the content will display below it.

Next, create a `div` tag and render an `Outlet` component. This is us telling `react-router` where to render the newly nested route.

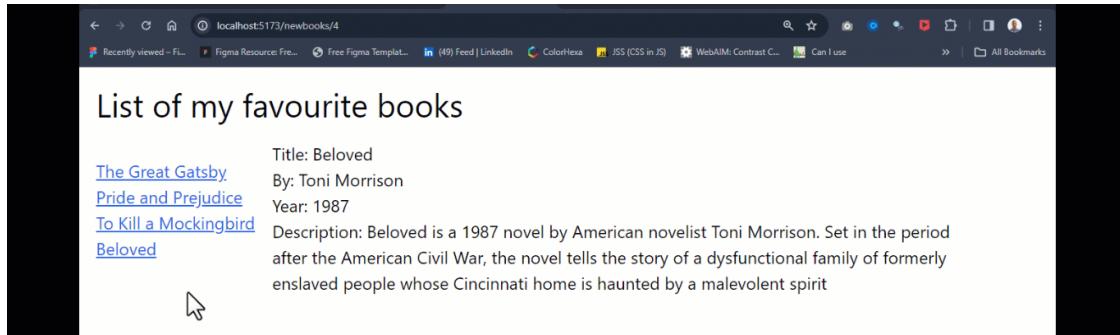

```
return (
  <>
  <div className='m-4'>
    <p className="text-3xl">`List of my favourite books`</p>
  </div>

  ↪ <section className='flex'>
    <div className='m-4'>
      {
        books && books.map((book)=> (
          <>
          <ul>
            <li>
              <Link to={`newbooks/${book.id}`} className='text-blue-600 underline'>{t
            </li>
          </ul>
        </>
      ))
    }
    </div>
    <div className='w-[70%]'>
      ↪ <Outlet />
    </div>
  
```

Support our charity and our mission. Donate to freeCodeCamp.org.

Note that to render the nested `FavBook` component side by side, both the outlet and the book list tag are nested in a section tag, and a style of display flex is applied.

Your code should look like this in your browser:

From the browser output, you can see that each listed item functions as a tab, and clicking them renders out the content of the API.

You've learned how to create a dynamic segment. In the next section, we'll build a project to help cement what we've learned even further.

Project: Build an Art Gallery

In this project, we are going to build an art gallery app that contains a list of sculpture and art from different countries. This will help you solidify the concepts you've previously learned.

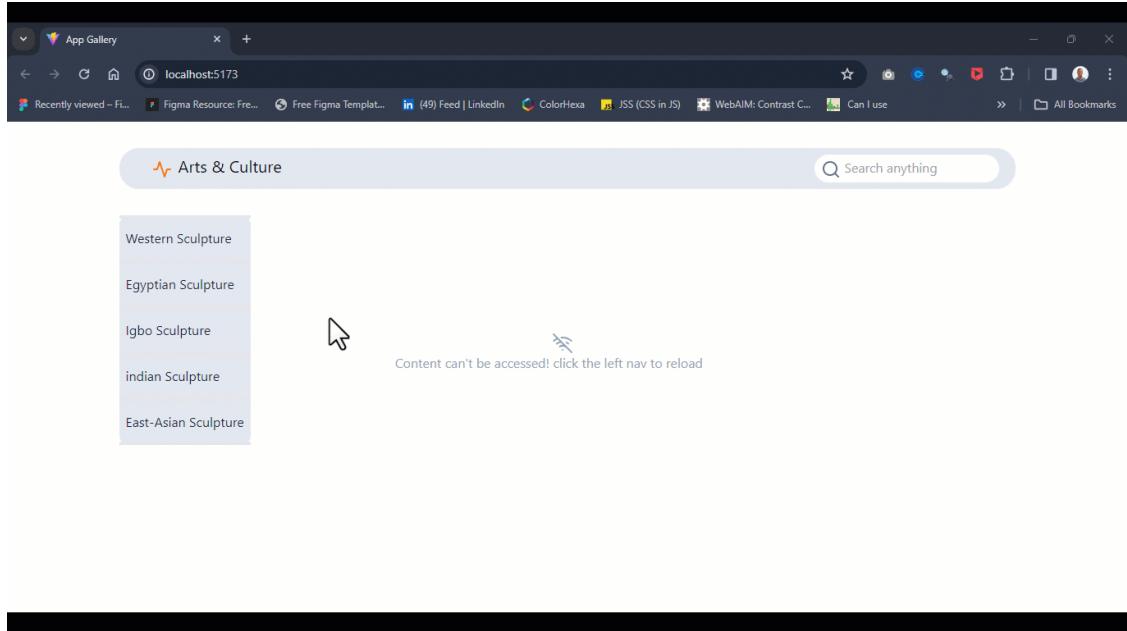

We are going to implement the following features:

- Client Side Routing
- Active Links
- Dynamic Segments
- Nested Routes

Below is a quick overview of what the project will look like.

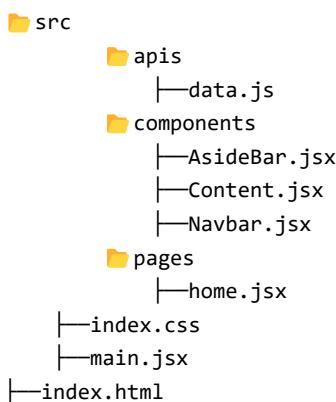

Support our charity and our mission. Donate to freeCodeCamp.org.

[Source code on !\[\]\(115eff7009a76771e6b7adb966005e4c_img.jpg\) GitHub here.](#)

Folder Structure

This is what the project's folder structure should look like:

How to Set Up the Home Page

To set up the home page, create a home component `./src/pages/home.jsx` and add the code below:

```

    └── home.jsx
  
```

Support our charity and our mission. Donate to freeCodeCamp.org.

```

        <section>
            <p className="text-orange-600">Hello World</p>
        </section>
    </main>
</>
)
}

```

Next, go to the `main.jsx` component. If you don't have one yet, create it as `./src/main.jsx`. then configure the route as follows:

|—main.jsx

```

import React from 'react'
import ReactDOM from 'react-dom/client'
import './index.css';

import {
    RouterProvider,
    createBrowserRouter,
    createRoutesFromElements,
    Route
} from 'react-router-dom';

import Home from './pages/home';

const router = createBrowserRouter(
    createRoutesFromElements(
        <Route path="/" element={<Home />}>

        </Route>
    )
)

ReactDOM.createRoot(document.getElementById('root')).render(
    <React.StrictMode>
        <RouterProvider router={router} />
    </React.StrictMode>,
)

```

Next, type `npm run dev` to launch your app.

Your app should look like this in your browser:

Support our charity and our mission. Donate to freeCodeCamp.org.

Hello World

How to Create and Style the Navbar

Now that we have the home and route component set up, let's create the navbar component, which is the top component in our app.

Create a component `./src/components/navbar.jsx` and add the code below:

|—navbar.jsx

```
import { Activity, Search } from "react-feather";

export default function Navbar() {
  return (
    <>
    <main className="">
      <header>
        <nav className="flex justify-between bg-slate-200 rounded-3xl py-2">
          {/* logo */}
          <div className="">
            <Activity className="inline-block ml-10 mr-2 text-orange-500" />
            <p className="inline-block text-xl">`Arts & Culture`</p>
          </div>

          {/* Navlinks */}
          <div className="bg-white rounded-3xl py-1 px-2 mr-5">
            <Search className="inline-block mr-1 text-slate-500"/>
            <input type="search" id="site-search" name="q" placeholder="Search arts & culture..." />
          </div>
        </nav>
      </header>
    </main>
  </>
)
}
```

From the code above, the navbar is divided between the logo and the search bar.

- **The logo:** we import the *Activity Icons* as a component from the feather icons and apply some Tailwind CSS classes to style it. The icon is set to `inline-block` so that we can apply space to it. We apply `ml-10` and `mr-2`, which is

Support our charity and our mission. Donate to freeCodeCamp.org.

- **One search:** For the search bar, we also imported it from react icons as a component and applied the following styling: `inline-block mr-1 text-slate-500`. If you are having a hard time understanding Tailwind CSS classes you can read more about them from the docs [here](#).

To position the logo and search bar side by side, we set the parent header to display flex and justify-content of space-between to apply space in between the logo and search bar.

Next, add the navbar to the route as follows:

└─main.jsx

```
import React from 'react'
import ReactDOM from 'react-dom/client'
import './index.css'

import {
  RouterProvider,
  createBrowserRouter,
  createRoutesFromElements,
  Route
} from "react-router-dom"

👉 import Navbar from './components/Navbar'
    import Home from './pages/home'

const router = createBrowserRouter(
  createRoutesFromElements(
    <Route path='/' element={<Home />}>
      👈 <Route path='/' element={<Navbar />} />
    </Route>
  )
)

ReactDOM.createRoot(document.getElementById('root')).render(
  <React.StrictMode>
    <RouterProvider router={router} />
  </React.StrictMode>,
)
```

From the code above, the Navbar component is nested inside the Home components. This means we have to use an Outlet component to render the Navbar component.

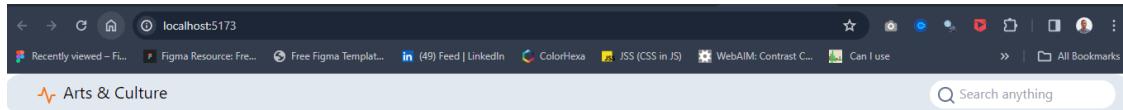

Next, go to the `./src/page/home` component, import, and replace the `<p>` with the `Outlet` component as indicated below:

Support our charity and our mission. Donate to freeCodeCamp.org.

```
👉 import { Outlet } from "react-router-dom";

export default function Home() {
  return (
    <>
      <main className="">
        <section>
         👉 <Outlet />
        </section>
      </main>
    </>
  )
}
```

Your app should look like this on your browser:

How to Create the AsideBar

The `AsideBar` is one of the most important components of our app. This is where the names of the cultures will be displayed. This component functions as a tab, and when a user clicks on it, it renders out more details about the culture that was clicked on.

Create a new component as `./src/components/AsideBar.jsx` and write in the code below:

|—AsideBar.jsx

```
import { NavLink } from "react-router-dom"
import data from "../apis/data"

export default function AsideBar() {

  const activeStyle = ({isActive}) => {
    return {
      backgroundColor : isActive ? "rgb(154 52 18)" : "",
      color : isActive ? "rgb(255 247 237)" : "",
    }
  }
}
```

Support our charity and our mission. Donate to freeCodeCamp.org.

```

        <section className="w-[100%]">
          <aside className="w-[fit-content] bg-slate-200 rounded-xl">
            {
              data.map((data)=>(
                <ul key={data.id}>
                  <li className="">
                    <NavLink className="w-[100%] py-3 px-2 inline-block 1
                      {data.type}
                    </NavLink>
                  </li>
                </ul>
              ))
            }
          </aside>
        </section>
      </main>
    </>
  )
}

```

From the code example above, we have our code split into two sections: the `data` and the `NavLink` component.

- **The data:** we imported the data from `./src/apis/data.js` and we are mapping each array of objects and returning the `data.type` as the names of the `AsideBar`.
- **The NavLink:** the data returned from `data.js` is rendered directly on the `NavLink` component. The `NavLink` component has two props specified, the `style` and `to` props. The `style` prop received the `activeStyle` object that indicated what style should be applied to `NavLink` when its active. The `to` prop `to={ content/${data.id} }` we pass the `data.id` as a segment to match with the `path` of the content components (*more on this in the next section*). This enables the content to dynamically render when the `NavLink` is clicked on.

Next, go to the home component and render the `AsideBar` as indicated below:

|—home.jsx

```

import { Outlet } from "react-router-dom";
👉 import AsideBar from "../components/AsideBar";

export default function Home() {
  return (
    <>
      <main className="w-[80%] mt-[2em] mx-auto">

```

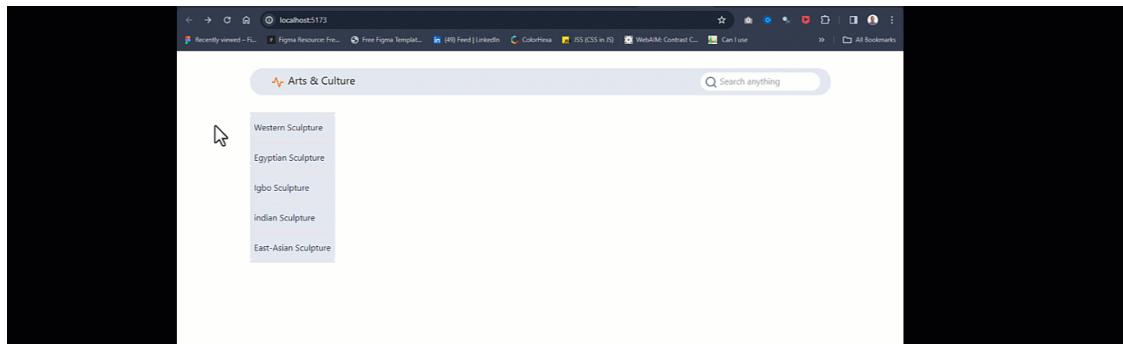

Support our charity and our mission. Donate to freeCodeCamp.org.

```

    <aside>
      ↗ <AsideBar />
    </aside>
  </section>
</main>
</>
)
}

```

Your app should look like this in your browser:

From interacting with the `AsideBar`, you may have noticed that the page breaks any time you click on the links. This is because the content component is not defined yet. So let's create it.

How to Create the Content Component

The content component renders the content that is related to a particular link that was clicked.

Create a new component called `./src/components/Content.jsx` and add the code below:

|—Content.jsx

```

import { Link, useParams } from "react-router-dom";
import data from "../apis/data.js";
import { WifiOff } from "react-feather";

export default function Content() {
  const {contentId} = useParams()

  const newData = data.find((data)=> data.id.toString() === contentId)

```

Support our charity and our mission. Donate to freeCodeCamp.org.

```
        <WifiOff className="text-slate-400 text-center translate-x-48"/>
        <p className="text-slate-400">{`Content can't be accessed! click the
      </div>
    </main>
  )
}

return (
<>
  <main className="w-[80%] mx-auto mt-8">
    <section >
      {
        newData && (
          <>
            {/* Image Over */}
            <aside className="h-[6em] w-[100%]">
              <div className="h-[100%] w-[100%]">
                <img src={newData.imgHeaders} alt="" className="h-[100%] w-[100%]" />
              </div>
            </aside>

            {/* Details */}
            <section className="flex gap-6">
              <aside className="w-[50%]">
                <div>
                  <p className="bg-orange-500 w-[fit-content] rounded-[10px] p-2">
                    <h1 className="font-light text-4xl my-7">{newData.type}</h1>
                    <p className="font-bold mb-4 text-2xl">{newData.region}</p>
                  </div>
                  <div>
                    <p className="font-light">{newData.history}</p>
                  </div>

                  <div className="mt-4">
                    <span>{`Learn more from`}</span>
                    <Link to={newData.britannicaLink} target="_blank" className="underline underline-offset-2 font-light" style={{color: "#0070C0", text-decoration: "none", cursor: "pointer", transition: "color 0.3s ease-in-out", border-bottom: "1px solid transparent", border-bottom-color: "#0070C0", border-bottom-style: "solid", border-bottom-width: "1px", padding-bottom: "0.5em", margin-bottom: "0.5em", display: "block", width: "100%"}>{newData.britannicaLink}</Link>
                  </div>
                </div>
              </aside>

              {/* Image Cover */}
              <aside className="w-[50%]">
                <div>
                  <img src={newData.imgCover} alt="" className="rounded-[10px] w-[100%] h-[100%]" />
                </div>
              </aside>
            </section>
          </>
        )
      }
    </section>
  </main>
</>
)
}
```

- **useParams:** we use the `useParams()` hook to return the key and value pairs of the dynamic segment `content/:contentId` specified on the route.
- **newData:** using the `find()` array method, the first element of the object array is returned if the condition is true, otherwise it returns `undefined`.
- **if(!contentId):** here, we are checking to see if the `contentId` doesn't match or is not rendered yet – then the provided element within the function should run. This is very useful for checking errors and in situations where the content is not available.
- **newData &&:** here we are mapping through the return data object and rendering the content of the API as soon as the content is loaded. Each object property is parsed into an element to render as content.

Next, go to the home component and render the content component as indicated below.

|—home.jsx

```
import { Outlet } from "react-router-dom";
import AsideBar from "../components/AsideBar";
👉 import Content from "../components/Content";

export default function Home() {
  return (
    <>
      <main className="w-[80%] mt-[2em] mx-auto">
        <section>
          <Outlet />
        </section>

        <section className="flex">
          <aside>
            <AsideBar />
          </aside>

          <aside>
            👈 <Content />
          </aside>
        </section>
      </main>
    </>
  )
}
```

Next, configure the route to a dynamic segment:

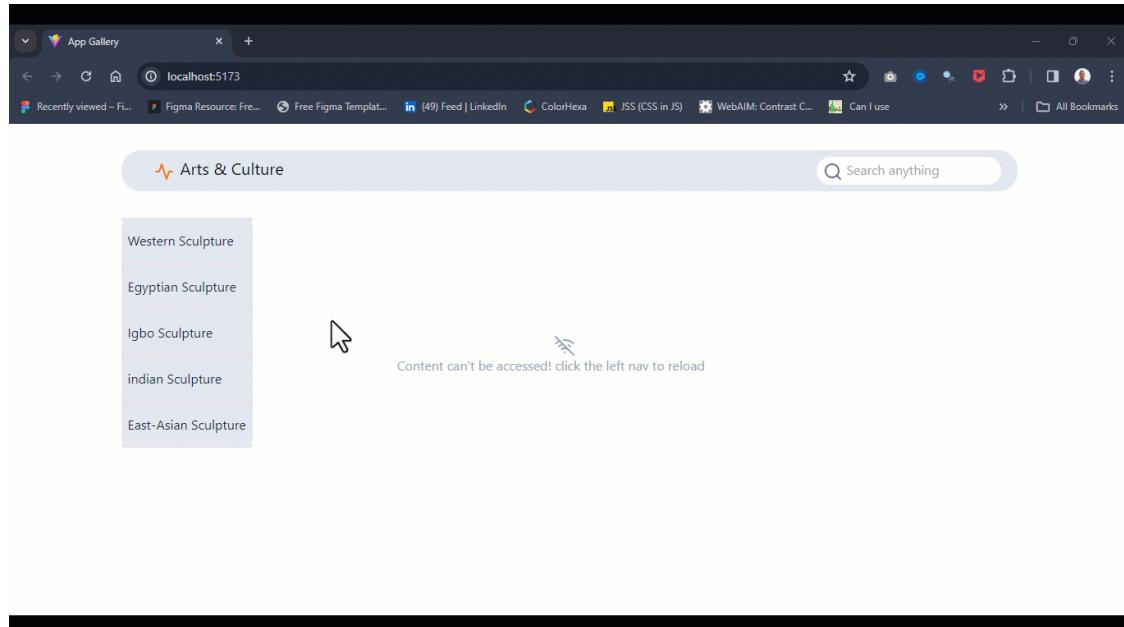

Support our charity and our mission. Donate to freeCodeCamp.org.

```
import Home from './pages/home';
import Navbar from './components/navbar';
👉 import Content from './components/Content';

const router = createBrowserRouter(
  createRoutesFromElements(
    <Route path='/' element={<Home />}>
      <Route path='/' element={<Navbar />}>
        👈 <Route path='content/:contentId' element={<Content />} />
      </Route>
    </Route>
  )
)

ReactDOM.createRoot(document.getElementById('root')).render(
  <React.StrictMode>
    <RouterProvider router={router} />
  </React.StrictMode>,
)
```

Your app should look just like this on your browser:

Clicking on the `Asidebar` will load the content from the API and render it on the same page as the `Asidebar`.

Summary

In this tutorial, we learned about Dynamic Segments in React Router. We talked about what Dynamic Router is and how it's different from static routing. You also

Support our charity and our mission. Donate to [freeCodeCamp.org](#).

Then we built a new project that dynamically rendered new content to the same page when the user clicks on the sidebar.

You can take this project further and make it your own by implementing more features.
